Exostoses are benign bony masses that develop in the external ear canal as a result of chronic exposure to cold water in the course of water sports or other immersion activities or work. The exostoses gradually expand, progressively blocking the canal, particularly if water penetrates deeply. Water and debris may cause persistent blockage, loss of hearing and infection. If troublesome, surgery is required to remove the obstructions.

The surgery uses a trans-canal approach (via the external canal, without major external incisions). The skin overlying the exostoses is carefully elevated, then the bony knobs are hollowed-out and removed. The canal skin is laid back in position and dressings are applied to stabilise the site during the healing phase, which takes 3-4 weeks.

- Exostoses

RISKS AND COMPLICATIONS

Delayed Healing

Due to the extent of the exostoses, the canal skin may have reduced in dimensions, or may be very thin, being very delicate and easily damaged during elevation. Fragile skin of this nature is easily torn during surgery. Loss of skin may result in delayed healing, particularly if infection intrudes. Expert care will reduce the likelihood of such problems, although limited grafting within the canal may be required to expedite healing.

Hearing

The surgery expects the best possible hearing outcome in almost all cases but this is sometimes not achieved, due to the extent of disease or other factors. Also although many cases have ringing (tinnitus) in the ears before surgery, this may not be eliminated and can be worse in a minority.

Generally, the hearing recovers after removal of the external canal dressings (3 weeks after).
Dizziness

Balance upsets after this surgery is very rare, but in some cases of more advanced disease the balance organs are traumatised during removal of disease or similar actions in the course of the surgery. Fortunately this generally fades, perhaps over a two-month course.

Facial Nerve Paralysis

Even in expert hands paralysis of the side of the face may occur for a variety of reasons in ear surgery, in less than 1-1000 cases.

Paralysis may last several months and then recover completely or partially. Temporary paralysis may also occur from local anaesthetic injection, lasting a few hours and then recovering. Eye irritation from these incidents may require an ophthalmologist’s care.

Drum Perforation

Generally in exostosis surgery the drum is not traumatised, but in severe cases where the exostoses press on the drum itself, minor damage may occur during removal. Limited reparative surgery to overcome the problem is fortunately relatively rare.

Taste Disturbance

The chorda tympani is the nerve that provides taste sensation to the side of the tongue. It passes near the field of surgery and may be bruised or cut in the course of the procedure. Taste disturbance occurs in about 10% of cases and this may last for up to 12 months, a few remaining permanent, sometimes with slight dryness of the mouth.

Infection, Pain

The nature of surgery predisposes to general surgical risks but fortunately the ear is generally not troubled by these problems to a severe or prolonged extent.

Exostosis surgery causes some tissue reaction close to the jaw joint, and this may be stiff or sore for a limited period.
POSTOPERATIVE INSTRUCTIONS

External canal site

The ear bowl and canal will have dressings that may become moist from slight bloodstained discharge. Replace the ear bowl dressings as necessary, but leave to canal dressings unmolested until their removal, usually 3 weeks after surgery. Until removal of the dressings, avoid heavy exercise, to reduce perspiration moisture within the canal. Removal of dressings is usually brief and pain-free. Water sports are not possible until the canal is well healed: 4-6 weeks.

Antibiotics will be prescribed and provided prior to discharge. Take these as directed on the packet. Sometimes diarrhoea may occur; consult your pharmacist re medicine for this, but continue the antibiotics and take probiotics to help settle matters.

Pain, Discomfort

Analgesics will be given both in hospital and supplied at discharge. Pain after ear surgery is normally limited, but if concerned contact us for advice. Nausea is less common, but advise our staff if you require medicine for this.

Activities

- Rest well after surgery; recovery varies from person to person.
- Return to work when well; this is normally after a few days, unless dizziness or other problems intervene.
- The ear canal dressings are removed at 3 weeks after surgery, and the ear reviewed after that. Audiology is undertaken at two months. Subsequent reviews occur on an individual basis.

Our goal in Exostoses surgery is to deliver the best results with the greatest certainty and minimal distress. But in surgery there are no guarantees of success. If you have had a lesser result after surgery, we will do our best to treat the problem, hopefully overcoming this.

Please let is know at Queensland Otology if you have any concerns or questions, whether before or after:
